REC'D 01 AUG 2003

WIPO PCT

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Light Fitting

This invention relates to a light fitting, more particularly, but not limited to, a light fitting for providing variable colour output and to a method of providing variable light colour output from a light fitting.

Various attempts have been made to obtain a variable colour light output from a lamp, such as a gas discharge lamp. Although these examples provide variable light colour they are very costly to produce and consequently very expensive. Poor light output is also a problem.

It is an object of the present invention to address the above disadvantage.

According to a first aspect of the invention a lighting system comprises a lamp, a power control for the lamp, coloured cover means for the lamp and control means, wherein the coloured cover means is adapted to substantially surround the lamp and the control means are operable to move the cover means relative to the lamp.

Preferably, the cover means is a sleeve, preferably an at least partially translucent sleeve, preferably having open ends.

Preferably, the control means are operable to turn the cover means, preferably about a longitudinal axis thereof.

preferably to allow a substantially complete visible spectrum to be viewed by substantially one rotation of the cover means with respect to the lamp.

5 The differently coloured sections may be receivable in at least one pocket of the body section, which at least one pocket may be adapted to have a strip inserted therein. More than one colour of strip may be inserted into said pocket, preferably in order to change the colour of the
10 light shining therethrough in use. A number of the pockets may be arranged around the outer surface of the cover means, preferably extending along the length thereof.

15 The body section of the cover means may be made of a coloured translucent/transparent material. The body section may be made of a clear translucent/transparent material having a coloured medium applied thereto, potentially by a printing technique.

20

According to a second aspect of the invention there is provided a cover means as described in relation to the first aspect.

25 The invention extends to a kit comprising cover means and control means as described in the first aspect. The kit is preferably adapted to be retrofitted to an existing lamp.

30 The invention extends to education apparatus comprising a light fitting according to the first aspect having cover means to selectively cover part of the lamp.

The lamp and power control may be a standard fluorescent lamp and associated control apparatus. The lamp is preferably tube-shaped. The lamp may be half-silvered.

- 5 The control means may comprise a motor which may be an integral motor. The motor may drive a drive belt. The drive belt may be arranged, in use, to engage the cover means. The control means may be operable to drive the cover means at different speeds.

10

The drive belt is preferably adapted to engage a drive portion of the cover means, which drive portion may be a drive cap located at one end of the cover means.

- 15 The cover means is preferably tube-shaped, preferably having a generally circular cross-section, preferably to allow rotation thereof over the lamp.

20 The cover means preferably has a body section, which may extend substantially along the length of the cover means, that is translucent to allow light from the lamp to pass therethrough.

25 The body section of the cover means may have differently coloured sections, to allow the colour of light issuing from the lighting system to vary as the cover means moves relative to the lamp.

30 The differently coloured sections may be strips, which may extend longitudinally along the cover means.

The body section may incorporate a spectrum of differently coloured strips arranged around the cover means,

According to a third aspect of the invention a method of varying the colour of light output from a lamp comprises placing at least partially translucent cover means over a lamp to substantially surround the lamp and moving the
5 cover means relative to the lamp.

The cover means is preferably a sleeve placed over the lamp and preferably has an axis generally parallel to an axis of the lamp. The cover means is preferably rotated
10 around a substantially longitudinal axis thereof.

All of the features described herein may be combined with any of the above aspects, in any combination.

15 For a better understanding of the invention and to show how the same may be brought into effect, specific embodiments will now be described, only by way of example, with reference to the accompanying drawings, in which:

20

Figure 1 is a schematic perspective view of a standard luminaire for a fluorescent lamp with a motor fitted at one end thereof;

25 Figure 2 is a schematic exploded diagram showing a fluorescent lamp tube, a coloured sleeve for placing over the tube, a first end cap of the sleeve and a second, drive, end cap of the sleeve;

30 Figure 3 shows a partial schematic perspective view of a drive system for the coloured sleeve placed over the fluorescent tube; and

Figure 4 shows a partial schematic side view of an end section of a standard fluorescent lamp fitting.

A fluorescent lamp tube 10 (see Figure 2) is located within a coloured sleeve 12, the body of the latter being made of translucent material. A drive cap 14 of the sleeve 12 is driven by a drive belt 16 (see Figure 3), movement of which causes rotation of the sleeve 12 over the fluorescent lamp tube 10. As the sleeve 12 rotates variations in the colour in the translucent material cause variations in the colour of the light transmitted into a surrounding environment.

In more detail, a standard fluorescent lamp tube luminaire 18, as shown in Figure 1, has a cover 20, end caps 22a and 22b and body 24, for housing the electrical and electronic parts of the luminaire. In this embodiment, a motor 26 is secured in the end plate 22b, with a drive shaft 28 thereof (see Figure 3) extending into the luminaire 18. The drive shaft may be approximately 5cm long. The motor 26 may turn the drive shaft 28 at a speed of approximately 50 rpm.

As shown in Figure 3, the drive shaft 28 is engaged by the drive belt 16, the drive shaft 28 extends generally parallel to the length of the fluorescent lamp 10 in its normal orientation in the luminaire 18.

The drive cap 14 on the coloured sleeve 12 has peripheral rims in which to receive and retain the drive belt 16. The drive shaft 28 similarly has retaining means 30 for the drive belt 16 to prevent lateral movement of the drive belt 16 along the drive shaft 28 during rotation thereof.

The drive cap 14 may be made of nylon or another low friction material to allow relative movement of the drive cap 14 and the coloured sleeve 12 over the fluorescent lamp 10, which would typically be made of glass. Alternatively, the drive cap 14 may bear against a metal end section 32 (see Figure 4) of the fluorescent lamp 10. An end cap 15 at the opposite end of the coloured sleeve 12 to the drive cap 14 may also be made of nylon to provide low friction relative movement between the sleeve 12 and the fluorescent lamp 10. The drive cap 14 may be integral and/or may be placed inside the sleeve 12. The drive cap 14 may be the same shape as the end cap 14 and may have an inner flange to bear against the glass part of the fluorescent lamp 10.

The coloured sleeve 12 may have a body section between the drive cap 14 and the end cap 15 which is made of plastics material, such as PVC or acrylic for example. The body material may be itself coloured to allow transmission of light of a given a colour therethrough, for example red, yellow or blue light. Alternatively, the body of the sleeve 12 may be colourless with coloured ink, pigment or the like applied thereto, for example by a printing process. Alternatively, coloured plastics material may be secured to the body with adhesive. A further alternative is to provide pockets running along the length of the sleeve 12 into which coloured material, such as plastics material, may be inserted to provide the colour for the sleeve 12.

The coloured sleeve 12 may provide a single colour, or more preferably, a plurality of colours, as shown in

Figure 3, in which longitudinal strips of red, yellow and blue colour are provided. A further alternative would be to provide a spectrum of colour changing steadily through the visible spectrum around the circumference of the sleeve. The colour may also change along the length of the sleeve 12, by suitable printing or changes in material.

In use, a gearing ratio is provided between the narrow drive shaft 28 and the drive cap 14, such that a generally slow rotation of the sleeve 12 is seen. Thus, using the example of the sleeve 12 in Figure 2, which has equal sections of red, yellow and blue colouring a period of red coloured light would be emitted by the sleeve 12 followed by a smooth transition to a yellow colour and then a smooth transition to a blue colour and back to red. The variation in colour in this way provides a pleasing visual effect, which may also be relaxing, given correct selection of the transition between colours and the correct selection of the colours. The predominant colour transmitted at any one time is that adjacent the section of lamp directed away from the body 24 of the luminaire 18. Also, the fluorescent lamp 10 may have a silvered underside 34, as shown in Figure 2 and a white translucent upperside to provide a good spectrum of light. Using the half-silvered tube 10 allows the light emitted from the sleeve 12 to be directed away from the body 24 of the luminaire.

In addition to the retaining means 30 shown in Figure 3, different sizes of retaining means 30 could be provided on the drive shaft 28, in order to provide different gearing ratios between the drive shaft 28 and the drive cap 14.

This provides different speeds of rotation of the sleeve 12 and so provides different visual effects.

As well as the aesthetic uses mentioned above, the
5 coloured sleeve 12 mentioned above that is provided with a
spectrum of colour may be used in order to select a
particular colour, either in selecting colours for fashion
items such as clothing, or to select the colour of
interior, or exterior, surfaces in a building, during
10 decorating. In order to achieve this, the full spectrum
coloured sleeve is rotated using the system described
above. The colour transmitted by the sleeve using the
half-silvered tube 10 will change continuously at a given
point as the sleeve rotates. A user can select the
15 required colour by stopping the rotation of the motor 26
when a preferred colour is found.

A remote control device may be provided to start and stop
the motor 26.

20

A further alternative to those described above would be to
provide a plurality of the luminaires shown in Figure 1
having the coloured sleeve 12 and drive system described.
The luminaires could be arranged to rotate the sleeve 12
25 in each of the luminaires at the same speed with the same
transitions between colours to provide a much greater area
of coloured illumination.

A double luminaire may also be provided. One lamp in the
30 double luminaire may be a simple white lamp, whilst
another lamp may have the coloured sleeve 12 and drive
system for providing coloured effects. With that system a

user may select standard illumination with the white tube 10 or variable colour illumination with the sleeve 12.

Educational uses for the system can also be envisaged.

5 Where a red, blue and green coloured sleeve is provided and is used with a tube 10 having no silvering so that light emitted from the tube causes all three of the red, blue and yellow lights to be emitted at some point around the circumference of the tube. The effect whereby the
10 colours of the light combine to produce white light can be used to demonstrate to students the combination of different light colours leading to different coloured light, or leading to white light, when the combination of red, yellow and blue is used. This effect can also be
15 shown by inserting different coloured strips into the pockets mentioned above. By having a spiral arrangement of red, yellow and blue strips (none overlapping), it can be shown that the light emitted combines to produce white light. A lamp 10 may have a part with a spiral
20 arrangement and the longitudinal strips described above, to show the difference between the light outputs, i.e. white from the spiral and the particular colour exposed from the other. A box may be provided with a sliding cover to selectively reveal one side or the other.

25

The system described above for providing lighting which changes colour over time has aesthetic benefits and may also be used to create a particular mood. The transition between different colours may be adjusted by selecting
30 different colour transitions on the sleeve, or by selecting different speeds of rotation for the sleeve.

Using the sleeve 12 which has pockets along its length, different types of colour transition can be selected by a user by differently coloured strips, or even using the same coloured strips to provide the same colour continuously, even whilst the sleeve 12 is rotating.

The reader's attention is directed to all papers and documents which are filed concurrently with or previous to this specification in connection with this application and which are open to public inspection with this specification, and the contents of all such papers and documents are incorporated herein by reference.

All of the features disclosed in this specification (including any accompanying claims, abstract and drawings), and/or all of the steps of any method or process so disclosed, may be combined in any combination, except combinations where at least some of such features and/or steps are mutually exclusive.

Each feature disclosed in this specification (including any accompanying claims, abstract and drawings), may be replaced by alternative features serving the same, equivalent or similar purpose, unless expressly stated otherwise. Thus, unless expressly stated otherwise, each feature disclosed is one example only of a generic series of equivalent or similar features.

The invention is not restricted to the details of the foregoing embodiment(s). The invention extends to any novel one, or any novel combination, of the features disclosed in this specification (including any accompanying claims, abstract and drawings), or to any

novel one, or any novel combination, of the steps of any method or process so disclosed.

CLAIMS:

1. A lighting system comprises a lamp, a power control for the lamp, coloured cover means for the lamp and
5 control means, wherein the coloured cover means is adapted to substantially surround the lamp and the control means are operable to move the cover means relative to the lamp.
 2. A lighting system as claimed in claim 1, in which the
10 cover means is a sleeve.
 3. A lighting system as claimed in claim 2, in which the sleeve has open ends.
 - 15 4. A lighting system as claimed in any preceding claim, in which the control means are operable to turn the cover means about a longitudinal axis thereof.
 5. A lighting system as claimed in any preceding claim,
20 in which the lamp is half-silvered.
 6. A lighting system as claimed in any preceding claim, in which the control means comprise a motor which drives a drive belt.
 - 25 7. A lighting system as claimed in claim 6, in which the drive belt is adapted to engage a drive portion of the cover means.
 - 30 8. A lighting system as claimed in any preceding claim, in which the cover means has a body section.
-

9. A lighting system as claimed in claim 8, in which the body section of the cover means has differently coloured sections.

5 10. A lighting system as claimed in either claim 8 or claim 9, in which the body section incorporates a spectrum of differently coloured strips arranged around the cover means.

10 11. A lighting system as claimed in claim 10, in which the differently coloured sections are receivable in at least one pocket of the body section.

12. A cover means as claimed in any one of claims 1 to 11.
15

13. A kit comprising cover means and control means as claimed in any one of claims 1 to 11.

14. Educational apparatus comprising a light fitting
20 according to any one of claims 1 to 11 and having cover means to selectively cover part of the lamp.

15. A method of varying the colour of light output from a lamp comprises placing at least partially translucent
25 cover means over a lamp to substantially surround the lamp and moving the cover means relative to the lamp.

16. A lighting system substantially as described herein with reference to the accompanying drawings.

30

17. A method of varying the colour of light output from a lamp substantially as described herein with reference to the accompanying drawings.

Abstract
Light Fitting

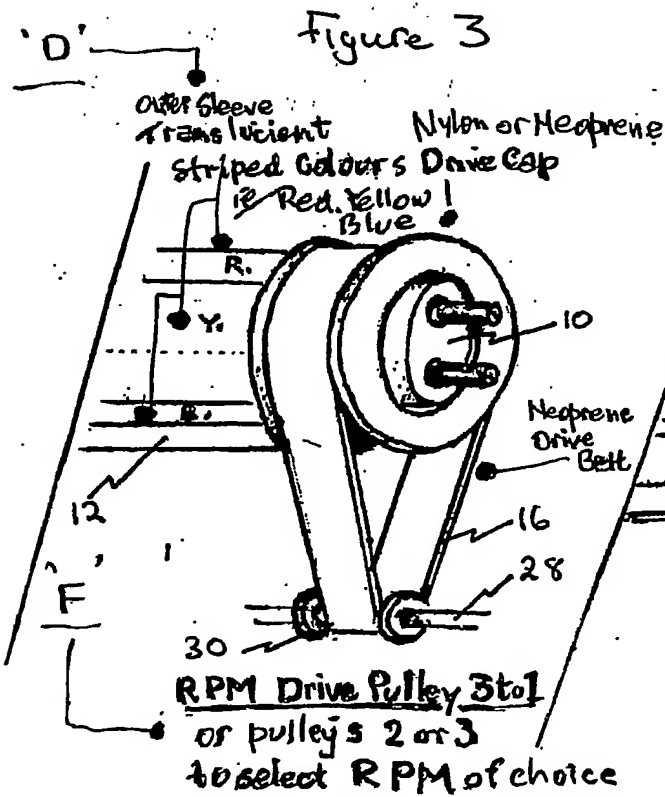

5 A fluorescent lamp 10 is located within a coloured sleeve 12, the body of the latter being made of translucent material. A drive cap 14 of the sleeve 12 is driven by a belt 16, movement of which causes rotation of the sleeve over the fluorescent lamp 10.
